## Definition

## Model

A mathematical model is a representation of a phenomena by means of mathematical equations. If the phenomena is growth, the corresponding model is called a growth model. Here we are going to study the following 3 models.

1. linear model
2. Exponential model
3. Power model

## 1. Linear model

The general form of a linear model is $y=a+b x$. Here both the variables $x$ and $y$ are of degree 1.

To fit a linear model of the form $\mathbf{y}=\mathbf{a + b x}$ to the given data.
Here $a$ and $b$ are the parameters (or) constants of the model. Let $\left(x_{1}, y_{1}\right)\left(x_{2}, y_{2}\right) \ldots \ldots \ldots \ldots$ $\left(\mathrm{x}_{\mathrm{n}}, \mathrm{y}_{\mathrm{n}}\right)$ be n pairs of observations. By plotting these points on an ordinary graph sheet, we get a collection of dots which is called a scatter diagram.

There are two types of linear models
(i) $y=a+b x$ (with constant term)
(ii) $\mathrm{y}=\mathrm{bx}$ (without constant term)

The graphs of the above models are given below :

' $a$ ' stands for the constant term which is the intercept made by the line on the $y$ axis. Wh $a=0$ $=0, y=a$ ie ' $a$ ' is the intercept, ' $b$ ' stands for the slope of the line .
Eg:1. The table below gives the DMP(kgs) of a particular crop taken at different stages; fit a linear growth model of the form $w=a+b t$, and find the value of $a$ and $b$ from the graph.

| t (in days) ; | 0 | 5 | 10 | 20 | 25 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| DMP w: (kg/ha) | 2 | 5 | 8 | 14 | 17 |

## 2. Exponential model

This model is of the form $y=a e^{b x}$ where $a$ and $b$ are constants to be determined The graph of an exponential model is given below.

## Note:

The above model is also known as a semilog model. When the values of $x$ and $y$ are plotted on a semilog graph sheet we will get a straight line. On the other hand if we plot the points xand y on an ordinary graph sheet we will get an exponential curve.
Eg: 2. Fit an exponential model to the following data.

| $x$ in days | 5 | 15 | 25 | 35 | 45 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $y$ in mg per plant | 0.05 | 0.4 | 2.97 | 21.93 | 162.06 |

## Power Model

The most general form of the power model is $y=a x^{b}$

0
X
Example: Fit the power function for the following data

| $x$ | 0 | 1 | 2 | 3 |
| :--- | :--- | :--- | :--- | :--- |
| $y$ | 0 | 2 | 16 | 54 |

## Crop Response models

The most commonly used crop response models are
i) Quadratic model
ii) Square root model

## Quadratic model

The general form of quadratic model is $y=a+b x+c x^{2}$

When $c<0$ the curve attains maximum at its peak.

$$
c<0
$$

When $\mathrm{c}>0$ the curve attains minimum at its peak.

The parabolic curve bends very sharply at the maximum or minimum points.

## Example

Draw a curve of the form $y=a+b x+c x^{2}$ using the following values of $x$ and $y$

| x | 0 | 1 | 2 | 4 | 5 | 6 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| y | 3 | 4 | 3 | -5 | -12 | -21 |

## Square root model

The standard form of the square root model is $y=a+b \sqrt{x}+c x$
When c is negative the curve attains maximum

The curve attains minimum when c is positive.

At the extreme points the curve bends at slower rate Three dimensional Analytical geometry

Let $O X, O Y \& O Z$ be mutually perpendicular straight lines meeting at a point $O$. The extension of these lines $O X^{1}, O Y^{1}$ and $O Z^{1}$ divide the space at $O$ into octants(eight). Here mutually perpendicular lines are called $X, Y$ and $Z$ co-ordinates axes and $O$ is the origin. The point $P(x, y, z)$ lies in space where $x, y$ and $z$ are called $x, y$ and $z$ coordinates respectively.

y
N
where $\mathrm{NR}=\mathrm{x}$ coordinate, $\mathrm{MN}=\mathrm{y}$ coordinate and $\mathrm{PN}=\mathrm{z}$ coordinate

## Distance between two points

The distance between two points $A\left(x_{1}, y_{1}, z_{1}\right)$ and $B\left(x_{2}, y_{2}, z_{2}\right)$ is

$$
\text { dist } \mathrm{AB}=\sqrt{\left(x_{2}-x_{1}\right)^{2}+\left(y_{2}-y_{1}\right)^{2}+\left(z_{2}-z_{1}\right)^{2}}
$$

In particular the distance between the origin $O(0,0,0)$ and a point $P(x, y, z)$ is

$$
\mathrm{OP}=\sqrt{x^{2}+y^{2}+z^{2}}
$$

The internal and External section
Suppose $\mathrm{P}\left(\mathrm{x}_{1}, \mathrm{y}_{1}, \mathrm{z}_{1}\right)$ and $\mathrm{Q}\left(\mathrm{x}_{2}, \mathrm{y}_{2}, \mathrm{z}_{2}\right)$ are two points in three dimensions.

$P\left(x_{1}, y_{1}, z_{1}\right)$
$A(x, y, z)$
$\mathrm{Q}\left(\mathrm{x}_{2}, \mathrm{y}_{2}, \mathrm{z}_{2}\right)$

The point $A(x, y, z)$ that divides distance $P Q$ internally in the ratio $m_{1}: m_{2}$ is given by

$$
\mathrm{A}=\left[\frac{m_{1} x_{2}+m_{2} x_{1}}{m_{1}+m_{2}}, \frac{m_{1} y_{2}+m_{2} y_{1}}{m_{1}+m_{2}}, \frac{m_{1} z_{2}+m_{2} z_{1}}{m_{1}+m_{2}}\right]
$$

Similarly
$P\left(x_{1}, y_{1}, z_{1}\right)$ and $Q\left(x_{2}, y_{2}, z_{2}\right)$ are two points in three dimensions.

The point $A(x, y, z)$ that divides distance $P Q$ externally in the ratio $m_{1}: m_{2}$ is given by

$$
\mathrm{A}=\left[\frac{m_{1} x_{2}-m_{2} x_{1}}{m_{1}-m_{2}}, \frac{m_{1} y_{2}-m_{2} y_{1}}{m_{1}-m_{2}}, \frac{m_{1} z_{2}-m_{2} z_{1}}{m_{1}-m_{2}}\right]
$$

If $A(x, y, z)$ is the midpoint then the ratio is $1: 1$

$$
\mathrm{A}=\left[\frac{x_{1}+x_{2}}{2}, \frac{y_{1}+y_{2}}{2}, \frac{z_{1}+z_{2}}{2}\right]
$$

## Problem

Find the distance between the points $P(1,2-1) \& Q(3,2,1)$
$\mathrm{PQ}=\sqrt{(3-1)^{2}+(2-2)^{2}+(1+1)^{2}}=\sqrt{2^{2}+2^{2}}=\sqrt{8}=2 \sqrt{2}$

## Direction Cosines

Let $\mathrm{P}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ be any point and $\mathrm{OP}=\mathrm{r}$. Let $\alpha, \beta, \gamma$ be the angle made by line OP with OX , OY \& OZ. Then $\alpha, \beta, \gamma$ are called the direction angles of the line OP. $\cos \alpha, \cos \beta, \cos \gamma$ are called the direction cosines (or dc's) of the line OP and are denoted by the symbols I, m,n.

## Result

By projecting OP on $\mathrm{OY}, \mathrm{PM}$ is perpendicular to y axis and the $\angle P O M=\beta$ also $\mathrm{OM}=\mathrm{y}$

$$
\therefore \cos \beta=\frac{y}{r}
$$

Similarly, $\quad \cos \alpha=\frac{x}{r}$

$$
\cos \gamma=\frac{Z}{r}
$$

(i.e) $I=\frac{x}{r}, m=\frac{y}{r}, n=\frac{z}{r}$

$$
\therefore r^{2}+m^{2}+n^{2}=\frac{x^{2}+y^{2}+z^{2}}{r^{2}}
$$

$\left(\because r=\sqrt{x^{2}+y^{2}+z^{2}} \Rightarrow\right.$ Distance from the origin $)$
$\therefore \mathrm{I}^{2}+\mathrm{m}^{2}+\mathrm{n}^{2}=\frac{x^{2}+y^{2}+z^{2}}{x^{2}+y^{2}+z^{2}}=1$
$\mathrm{r}^{2}+\mathrm{m}^{2}+\mathrm{n}^{2}=1$
(or) $\cos ^{2} \alpha+\cos ^{2} \beta+\cos ^{2} \gamma=1$.
Note
The direction cosines of the $x$ axis are $(1,0,0)$
The direction cosines of the $y$ axis are $(0,1,0)$
The direction cosines of the $z$ axis are $(0,0,1)$

## Direction ratios

Any quantities, which are proportional to the direction cosines of a line, are called direction ratios of that line. Direction ratios are denoted by $a, b, c$.

If $\mathrm{I}, \mathrm{m}, \mathrm{n}$ are direction cosines $\mathrm{an} \mathrm{a}, \mathrm{b}, \mathrm{c}$ are direction ratios then
$a \propto l, b \propto m, c \propto n$
(ie) $a=k l, b=k m, c=k n$
(ie) $\frac{a}{l}=\frac{b}{m}=\frac{c}{n}=k$ (Constant)
(or) $\frac{l}{a}=\frac{m}{b}=\frac{n}{c}=\frac{1}{k}$ (Constant)

## To find direction cosines if direction ratios are given

If $a, b, c$ are the direction ratios then direction cosines are

$$
\left.\begin{array}{rl}
\frac{l}{a}=\frac{1}{k} \Rightarrow & I  \tag{1}\\
\text { similarly } & =\frac{\boldsymbol{a}}{\boldsymbol{k}} \\
m & =\frac{\boldsymbol{b}}{\boldsymbol{k}} \\
n & =\frac{\boldsymbol{c}}{\boldsymbol{k}}
\end{array}\right\}
$$

$r+m^{2}+n^{2}=\frac{1}{k^{2}}\left(a^{2}+b^{2}+c^{2}\right)$
(ie) $1=\frac{1}{k^{2}}\left(a^{2}+b^{2}+c^{2}\right)$

$$
\Rightarrow k^{2}=a^{2}+b^{2}+c^{2}
$$

Taking square root on both sides

$$
\begin{aligned}
& \mathrm{K}=\sqrt{a^{2}+b^{2}+c^{2}} \\
& \therefore l=\frac{a}{\sqrt{a^{2}+b^{2}+c^{2}}}, \quad m=\frac{b}{\sqrt{a^{2}+b^{2}+c^{2}}}, \quad n=\frac{c}{\sqrt{a^{2}+b^{2}+c^{2}}}
\end{aligned}
$$

## Problem

1. Find the direction cosines of the line joining the point $(2,3,6) \&$ the origin.

## Solution

By the distance formula
$r=\sqrt{x^{2}+y^{2}+z^{2}}=\sqrt{2^{2}+3^{2}+6^{2}}=\sqrt{4+9+36}=\sqrt{49}=7 \quad z$

## Direction Cosines are

$$
\begin{array}{r}
I=\cos \alpha=\frac{x}{r}=\frac{2}{7} \\
m=\cos \beta=\frac{y}{r}=\frac{3}{7} \\
n=\cos \gamma=\frac{z}{r}=\frac{6}{7} \tag{X}
\end{array}
$$

2. Direction ratios of a line are $3,4,12$. Find direction cosines

## Solution

Direction ratios are 3,4,12
(ie) $a=3, b=4, c=12$
Direction cosines are

$$
\begin{gathered}
I=\frac{a}{\sqrt{a^{2}+b^{2}+c^{2}}}=\frac{3}{\sqrt{3^{2}+4^{2}+12^{2}}}=\frac{3}{\sqrt{169}}=\frac{3}{13} \\
m=\frac{b}{\sqrt{a^{2}+b^{2}+c^{2}}}=\frac{4}{\sqrt{3^{2}+4^{2}+12^{2}}}=\frac{4}{\sqrt{169}}=\frac{4}{13} \\
n=\frac{c}{\sqrt{a^{2}+b^{2}+c^{2}}}=\frac{12}{\sqrt{3^{2}+4^{2}+12^{2}}}=\frac{12}{\sqrt{169}}=\frac{12}{13}
\end{gathered}
$$

## Note

1) The direction ratios of the line joining the two points $A\left(x_{1}, y_{1}, z_{1}\right)$ \& $B\left(x_{2}, y_{2}, z_{2}\right)$ are $\left(x_{2}-x_{1}, y_{2}-y_{1}, z_{2}-z_{1}\right)$
2) The direction cosines of the line joining two points $A\left(x_{1}, y_{1}, z_{1}\right) \&$
$\mathrm{B}\left(\mathrm{x}_{2}, \mathrm{y}_{2}, \mathrm{z}_{2}\right)$ are $\frac{x_{2}-x_{1}}{r}, \frac{y_{2}-y_{1}}{r}, \frac{z_{2}-z_{1}}{r}$
$r=$ distance between $A B$.
